**Problem Statement**

Employees spend a significant portion of their workweek searching for internal information—ranging from HR policies to technical Standard Operating Procedures (SOPs)—across scattered platforms. This disjointed knowledge management causes severe productivity loss, frustrates employees, and constantly interrupts senior staff and HR with repetitive questions.

**Current Process & Detailed Pain Points**

Currently, when an employee needs to know how to process a refund, apply for leave, or configure a system, they must manually search through a messy combination of Google Drive folders, intranet pages, and PDF manuals. If the keyword search fails, they interrupt a manager or HR representative via Slack or email and wait for an answer.

**Detailed Pain Points:**

- **Information Silos & Search Friction:** Standard keyword searches often fail because they require exact phrasing. An employee searching for "time off" might miss a document titled "Leave Absence Policy," leading to dead ends.
- **The "Shoulder-Tap" Productivity Drain:** Senior engineers, HR teams, and managers are constantly bombarded with repetitive, easily answerable questions. This constant context-switching destroys deep-work focus and costs the company thousands of dollars in wasted high-level hours.
- **Outdated Information Reliance:** Because finding the right document is hard, employees often rely on memory or ask peers, which frequently results in them following outdated policies or deprecated SOPs.
- **The Hallucination Risk:** Standard LLMs cannot be used safely for internal queries because they will "hallucinate" or invent company policies that do not actually exist, creating legal or operational liabilities.

**Proposed Solution Outline**

- **Vector Database Architecture:** Ingest company policies, SOPs, and internal documents, convert them into vector embeddings, and store them in a Vector DB
- **RAG (Retrieval-Augmented Generation) Pipeline:** When an employee asks a question, the system will search the Vector DB for the exact relevant paragraphs and feed *only* that factual context to the LLM to generate an answer.

- **Source-Aware Citations:** The AI will be strictly prompted to append a link or citation to the exact internal document it used to formulate its answer, establishing trust.
- **Fallback & Human Escalation:** If the Vector DB search returns no relevant results, the AI will trigger a strict "Unknown-answer fallback" rule (e.g., "I do not have access to this information"). It will then automatically create a support ticket and route it to the correct human department.

**Success Criteria**

- **Zero-Hallucination Rate:** The AI must explicitly state "I don't know" rather than inventing a policy when the information is missing from the vector database.
- **Speed & Offloading:** Reduce the time it takes an employee to find a policy from 15+ minutes to under 5 seconds.
- **Deflection Rate:** Reduce the volume of routine informational tickets/messages sent to HR and Management by at least 40%.
